

**ISSPRO 3 3/8" DIA. Programmable Tachometer
High Performance EV Line
Part Numbers R5535M, R6535M**

General Information:

Operating Voltage:

11-30VDC (12V or 24V system configurable): NOTE-Instrument comes equipped with 12 volt lamps. Replace lamps with ones supplied when installing instrument into 24V system.

Input Signal:

Magnetic Gear tooth sensor, AC generator, Alternator tap, 5 volt signal from computer.

Programming Range:

1 TO 280 Pulses per engine revolution (gear teeth, magnets, etc.).

Transient Protection:

Conforms to SAE J1113 specifications for steady state and electrical transient testing.

This part is reverse polarity protected.

Calibration:

The tachometer is configured by setting a 10 position dip-switch to the calibration number. The switch is located under a plate on the rear of the unit and is accessible by removing two screws.

Note: Power must be cycled OFF to ON before the tachometer will accept a change in calibration.

Calibration Number:

Calibration number is the number of pulses per engine revolution from the alternator, magnetic sensor or signal generator.

Alternator Input:

The tachometer is connected to the "w" terminal (stator tap) on the alternator. Note that some alternators may use "S" or "T" to indicate the tachometer tap. Some alternators do not have a connection to the stator to give a tachometer output. These alternator types must be modified or replaced for use with this tachometer.

Calibration number for an alternator application is:

$$\text{Calibration number} = \frac{\# \text{ Poles of Alternator} \times \text{Dia. of crank pulley}}{2 \text{ Dia of alternator pulley}}$$

Note: The poles of an alternator are the metal fingers around the rotating field winding in the center of the alternator.

Magnetic Sensor Input:

(Variable Reluctance type)

These sensors give a voltage pulse whenever a gear tooth is detected. If a flywheel is used, the calibration number is number of teeth on the flywheel. If a different gear is used, it is important to know how fast the gear rotates in relation to the engine. If the gear runs half the speed of the engine, the calibration number is half the number of teeth. On these types of sensors, it is important that the sensing portion of the sensor (round or square portion in the middle of the sensing end) be smaller than the distance between the gear teeth for adequate output. Installation requires that the sensor be set as close to the gear teeth as possible. Usually (with engine OFF) screw the sensor in until it touches the gear then back off 1/2 turn.

Proximity Sensor Input:

There are a number of different types of these sensors. The simplest is two magnets glued to the vibration damper with the sensor mounted near the magnets. Calibration number is determined the same way as the magnetic sensors. The two-magnet device gives a calibration number of two.

Signal Generator Input:

Generator is installed on tachometer cable drive of engine.

These come in a number of different configurations and styles. The ISSPRO R8940 and R8970 are typical sensors and give 30 pulses per their revolution. To determine calibration number, multiply the pulses per turn times the

drive ratio. Example: Cam drive of 0.5 revolutions per engine revolution and an R8970 give a calibration number of 15.

It is important to use a sensor that gives a whole calibration number. Fractions will make the tachometer inaccurate.

If it is not possible to determine the calibration number by any method described above, it is possible to use an optical tachometer to get the actual RPM . Use the following method to set the tachometer:

$$\text{New calibration number} = \frac{\text{switch setting number} \times \text{Correct RPM reading}}{\text{Indicated tachometer reading}}$$

Setting the Tachometer:

Remove the switch access cover, located at the rear of the unit, by removing the two hold down screws. (See illustration)

Locate the calibration number on the Calibration Chart to determine switch position. Example: For a 3500RPM FSD (Full Scale Deflection) tachometer, a calibration number of 45 gives a switch setting of 2,3,4,5 and 8 ON. All other switches are OFF.

Note that the switch setting will only be accepted when power is cycled from OFF to ON.

Replace the switch access cover and screws. Do not over tighten screws.

Installation:

Make all connections to the supplied plug before connecting to the tachometer. When mounting, the recommended hole size is 3.32" diameter.

Connect the tachometer wiring as follows:

Red wire: Battery positive. (Does not lose power with ignition OFF).
Black wire: Ground wire and one sensor wire.
Blue wire: Ignition voltage (Only has power when ignition switch is ON).
Green wire: Tach signal from sensor or alternator.
White wire: Dashboard illumination.

WARNING: Gauge has 12V light bulbs installed, 24V applications need to follow lamp replacement instruction

Mount the tachometer into the dash panel.

Testing:

Confirm operation of the tachometer by starting the engine. When the ignition is "OFF" the pointer is free to move to any position. When ignition is applied, the pointer will move to its appropriate position.

Lamp Replacement:

Remove the two rubber caps by pulling while gently rotating. Remove the lamp holders by rotating counter clockwise. The lamp can be removed from the holder by pulling it.
